

# Problem Set 5, Data Structures

Jay R Bolton

December 15, 2011

Set 5: 5.1, 5.5, 5.14, 5.15

**5.1** (a)

<b>Index</b>	<b>Key</b>
1	4371
2	
3	1323, 6173
4	4344
5	
6	
7	
8	
9	4199, 9679, 1989

(b)

<b>Index</b>	<b>Key</b>
1	4371
2	9679
3	1323
4	6173
5	4344
6	1989
7	
8	
9	4199

(c)

<b>Index</b>	<b>Key</b>
1	4371
2	9679
3	1323
4	6173
5	4344
6	
7	
8	9679
9	4199

(d) I guess I'll assume it's linear probing.

Index	Key
1	
2	
3	4344
4	1323
5	6173
6	4371
7	4199
8	9679
9	1989

**5.5** I assume he's talking about the collision function for open addressing (probing with a set of random numbers?).

- (a) If  $n$  is the length of our hash table, and  $i$  maps to  $0..x$  where  $x$  is the parameter that resolved an open bucket, then  $f(i)$  can probe  $0..n-1$  and return indexes for  $n$  different buckets, so that every bucket in the hash table will be potentially tried.
- (b) Probably.
- (c) In my copy of the book, the load factor figures are red X boxes (missing image), so I could try to generalize. If the load factor is low, say 0.25, then the initial probe will have a  $1/4$  chance of colliding. If it was higher, such as .75, then there would be a  $3/4$  chance of colliding. The load factor of the table then plays a big part in probing time.
- (e) You could start out with a list of integers,  $[1..n]$ , and iterate  $n$  times. On each iteration, generate a random number modulo  $n-1$ , retrieve and remove that element from the list. I don't know what  $P$  refers to.

**5.14**

Index	Key
000	00000010, 00001011
001	00101011
010	01010001
011	01111111, 01100001
100	10011011, 10010110, 10011110
101	10111101, 10111110,
110	11001111, 11011011
111	11110000

**5.15** `insert(key, hash)`  
`index := f(key)` where  $f$  is the hashing function  
`if (size(index(hash,index)) > hash->m)`  
`hash := expand(hash)`  
`insert(key, hash)`  
`else append bucket at index(hash,index) with key`

```
expand(hash)
    allocate new hash of double size
    create new hash function based on the new size
    iterate through each element of the old hash,
    reinserting each key into the new hash.
```

Its performance for lookups will be much better, because collision searches are likely to be much shorter. However, the act of extending the table will likely be very expensive.
